

This week I was the data person on our SquatCheck team, so I handled all the backend stuff. I built `app.py`, which is our Flask server, and wired up all six routes we need: the home page, a start button, the lesson pages (`/learn/1` through `/learn/5`), the quiz pages, a `/submit-answer` endpoint that takes JSON from the frontend, and the final `/result` page. I also wrote all the actual content `lessons.json` has the 5 teaching pages (intro, 3 things to watch from the side, heel position, forward lean, lumbar flexion), and `quiz.json` has all 3 quiz questions with their answer keys. I made sure the answer keys stay on the server and never get sent to the browser, so people can't just inspect the HTML and cheat

The scoring logic handles all three question types (multi-select, single-select, and true/false). I also added a little logger that prints the session state after every request, which helps Sofia when she's testing that answers are actually being stored.

I committed everything to a `sam/data-architecture` branch and pushed it up to GitHub so Jolie and Sofia can review before it goes to main :)
